COMPLETE THE STN SURVEY - APRIL 27 THROUGH MAY 31

Dear valued STN customer,

In an effort to enhance your experience with STN, we would like to better understand what you find useful. Please take approximately 5 minutes to complete a web survey.

If you provide us with your name, login ID, and e-mail address, you will be entered in a drawing to win a free iPod(R). Your responses will be kept confidential and will help us make future improvements to STN.

Take survey: http://www.zoomerang.com/survey.zgi?p=WEB2259HNKWTUW

Thank you in advance for your participation.

AB Monomeric **sarcosine oxidase** (MSOX) binds the L-**proline** zwitterion (pKa = 10.6). The reactive substrate anion is generated by ionization of the ES complex (pKa = 8.0). Tyr317 was mutated to Phe to determine whether this step might involve proton transfer to an active site base. The mutation does not eliminate the ionizable group in the ES complex (pKa = 8.9) but does cause a 20-fold decrease in the maximum rate of the reductive half-reaction. Kinetically determined Kd values for the ES complex formed with L-**proline** agree with results obtained in spectral titrations with the wild-type or **mutant** enzyme. Unlike the wild-type enzyme, Kd values with the **mutant** enzyme are pH-dependent, suggesting that the mutation has perturbed the pKa of a group that affects the Kd. As compared with the wild-type enzyme, an increase in charge transfer band energy is observed for **mutant** enzyme complexes with substrate analogues while a 10-fold decrease in the charge transfer band extinction coefficient is found for the complex with the L-**proline** anion. The results eliminate Tyr317 as a possible acceptor of the proton released upon substrate ionization. Since previous studies rule out the only other nearby base, we conclude that L-**proline** is the ionizable group in the ES complex and that amino acids are activated for oxidation upon binding to MSOX by stabilization of the reactive substrate anion. Tyr317 may play a role in substrate activation and optimizing binding, as judged by the effects of its mutation on the observed pKa, reaction rates, and charge transfer bands.

AB Conservative mutation of His269 (to Asn, Ala, or Gln) does not significantly affect the expression of monomeric **sarcosine oxidase** (MSOX), covalent flavinylation, the physicochemical properties of bound FAD, or the overall protein structure. Turnover with sarcosine and the limiting rate of the reductive half-reaction with L-**proline** at pH 8.0 are, however, nearly 2 orders of magnitude slower than that with with wild-type MSOX. The crystal structure of the His269Asn complex with pyrrole-2-carboxylate shows that the pyrrole ring of the inhibitor is displaced as compared with wild-type MSOX. The His269

mutants all form charge-transfer complexes with pyrrole-2-carboxylate or methylthioacetate, but the charge-transfer bands are shifted to shorter wavelengths (higher energy) as compared with wild-type MSOX. Both wild-type MSOX and the His269Asn mutant bind the zwitterionic form of L-proline. The E(ox).L-proline complex formed with the His269Asn mutant or wild-type MSOX contains an ionizable group (pK(a) = 8.0) that is required for conversion of the zwitterionic L-proline to the reactive anionic form, indicating that His269 is not the active-site base. We propose that the change in ligand orientation observed upon mutation of His269 results in a less than optimal overlap of the highest occupied orbital of the ligand with the lowest unoccupied orbital of the flavin. The postulated effect on orbital overlap may account for the increased energy of charge-transfer bands and the slower rates of electron transfer observed for mutant enzyme complexes with charge-transfer ligands and substrates, respectively.

AB Modified **sarcosine oxidase** having improved stability in the liquid state compared with the unmodified one and/or having a lowered activity on L-**proline** compared with the unmodified one and having an excellent substrate specificity without losing the **sarcosine oxidase** activity, and use as creatine assay reagent, are disclosed. A process for producing **sarcosine oxidase** which comprises culturing a microorganism capable of producing **sarcosine oxidase** and collecting the **sarcosine oxidase** from the culture medium; is also claimed. Such modified **sarcosine oxidase** have at

least one of the following characteristics, i.e., an activity on L-proline being 0.7% or less based on sarcosine and a Km value to L-proline being 150 mM or more, when measured at 37° and pH 8.0;. A mutant of Arthrobacter strain TE1826 sarcosine oxidase was prepared by substituting various residues to reduce its reactivity to Pro, which causes errors during the determination of creatine or creatine in body fluid. The Pro reactivity of the mutants was reduced by >70%.

AB Monomeric **sarcosine oxidase** (MSOX) binds the L-**proline** zwitterion (pK (a) = 10.6). The reactive substrate anion is generated by ionization of the ES complex (pK(a) = 8.0). Tyr317 was mutated to Phe to determine whether this step might involve proton transfer to an active site base. The mutation does not eliminate the ionizable group in the ES complex (pK (a) = 8.9) but does cause a 20-fold decrease in the maximum rate of the reductive half-reaction. Kinetically determined K(d) values for the ES complex formed with L-**proline** agree with results obtained in spectral titrations with the wild-type or **mutant** enzyme. Unlike the wild-type enzyme, K(d) values with the **mutant** enzyme are pH-dependent, suggesting that the mutation has perturbed the pK(a) of a group that affects the K (d). As compared with the wild-type enzyme, an increase in charge transfer band energy is observed for **mutant** enzyme complexes with substrate analogues while a 10-fold decrease in the charge transfer band extinction coefficient is found for the complex with the L-**proline** anion. The results eliminate Tyr317 as a possible acceptor of the proton released upon substrate ionization. Since previous studies rule out the only other nearby base, we conclude that L-**proline** is the ionizable group in the ES complex and that amino acids are activated for oxidation upon binding to MSOX by stabilization of the reactive substrate anion. Tyr317 may play a role in substrate activation and optimizing binding, as judged by the effects of its mutation on the observed pK(a), reaction rates, and charge transfer bands. .COPYRGT. 2005 American Chemical Society.

AB Conservative mutation of His269 (to Asn, Ala, or Gln) does not-significantly affect the expression of monomeric **sarcosine oxidase** (MSOX), covalent flavinylation, the physicochemical properties of bound FAD, or the overall protein structure. Turnover with sarcosine and the limiting rate of the reductive half-reaction with L-**proline** at pH 8.0 are, however, nearly 2 orders of magnitude slower than that with with wild-type MSOX. The crystal structure of the His269Asn complex with pyrrole-2-carboxylate shows that the pyrrole ring of the inhibitor is displaced as compared with wild-type MSOX. The His269 **mutants** all form charge-transfer complexes with pyrrole-2-carboxylate or methylthioacetate, but the charge-transfer bands are shifted to shorter wavelengths (higher energy) as compared with wild-type MSOX. Both wild-type MSOX and the His269Asn **mutant** bind the zwitterionic form of L-**proline**. The E(ox).ovrhdot.L-**proline** complex formed with the His269Asn **mutant** or wild-type MSOX contains an ionizable group (pK(a) = 8.0) that is required for conversion of the zwitterionic L-**proline** to the reactive anionic form, indicating that His269 is not the active-site base. We propose that the change in ligand orientation observed upon mutation of His269 results in a less than optimal overlap of the highest occupied orbital of the ligand with the lowest unoccupied orbital of the flavin. The postulated effect on orbital overlap may account for the increased energy of charge-transfer bands and the slower rates of electron transfer observed for **mutant** enzyme complexes with charge-transfer ligands and substrates, respectively.
